## $3 e 2.14$

2.14 The number of parity bits is minimized by making the array as close as possible to square, so the number of parity bits is on the order of $2 \sqrt{n}+1$. The exact answer depends on the value of $n$, and will be either $2\lceil\sqrt{n}\rceil$ (e.g., for $10 \leq n \leq 12$ or $2\lceil\sqrt{n}\rceil+1$ (e.g., for $13 \leq n \leq 16$ ).

2.19 Assuming that the solution $x=8$ is correct in some base $b>8$, we can write the following equation using base-10 arithmetic:

$$
5 \cdot 8^{2}+(5 \cdot b+0) \cdot 8+1 \cdot b^{2}+2 \cdot b+5=0
$$

Solving the quadratic, we get $b=13$ or $b=25$. Next, we try the $x=5$ solution for both possible bases, and find that it works only for $b=13$; the Martians had 13 fingers.

2.21 The result follows directly from Tables $2-1$ and $2-3$. For any 4-bit string $B$ and corresponding hex digit $H$, the ones' complement of $B$ is represented by the 15 s ' complement of $H$. Since the ones' complement is obtained by complementing individual bits, we can complement them in groups of four to arrive at the result.

2.22 Cases 1 and 2 assume no overflow.

Case $1(x, y \geq 0)$ :

$$
\begin{aligned}
& {[x+y]=x+y } \\
&=[x]+[y] \\
& {[x+y]=} 2^{n}-(|x|+|y|) \\
&= 2^{n}+2^{n}-(|x|+|y|) \text { modulo } 2^{n} \\
&=\left(2^{n}-|x|\right)+\left(2^{n}-|y|\right) \\
&= {[x]+[y] }
\end{aligned}
$$

Case $3(x<0, y \geq 0)$ :

$$
[x+y]=0
$$

subcase 3a: $|x|=|y|$, so $x+y=0$

$$
=2^{n} \text { modulo } 2^{n}
$$

$$
=\left(2^{n}-|x|\right)+|y|
$$

$$
=[x]+[y]
$$

$$
[x+y]=2^{n}-(|x|-|y|) \text { (using signed-magnitude rules) }
$$

subcase 3b: $|x|>|y|$, so $x+y<0 \quad=\left(2^{n}-|x|\right)+|y|$

$$
=[x]+[y]
$$

Case $4(x \geq 0, y<0):|x| \geq|y|$, so $x+y \geq 0$

2.23 If $x<0$, then $[x]=2^{n}-1-|x|$. We want to show that $[x+y]=[x]+[y] \operatorname{modulo}^{n}-1$.

Cases 1 and 2 assume no overflow.
Case $1(x, y \geq 0)$ :

$$
\begin{aligned}
|x+y| & =x+y \\
& =|x|+|y|
\end{aligned}
$$

$$
\begin{aligned}
{[x+y] } & =x+y \\
& =\left(2^{n}-1+2^{n}-1-(|x|+|y|) \bmod \text { ulo } 2^{n}-1\right) \\
& =\left(\left(2^{n}-1-|x|\right)+\left(2^{n}-1-|y|\right)\right) \\
& =x+y
\end{aligned}
$$

Case $2(x, y<0)$ :

Case $3(x<0, y \geq 0)$ :

$$
\begin{aligned}
{[x]+|y| } & =0 \\
& =2^{n}-1 \text { modulo } 2^{n}-1 \\
& =2^{n}-1-|x|+|x| \\
& =\left(2^{n}-1-|x|\right)+|y| \\
& =[x]+[y]
\end{aligned}
$$

subcase 3a: $|x|=|y|$, so $x+y=0 \quad=2^{n}-1-|x|+|x|$

$$
[x+y]=2^{n}-1-(|x|-|y|) \text { (using signed-magnitude rules) }
$$

subcase $3 \mathrm{~b}:|x|=|y|$, so $x+y<0$

$$
\begin{aligned}
& =\left(2^{n}-1-|x|\right)+y \\
& =x+y
\end{aligned}
$$

Case $4(x \geq 0, y<0):|x| \geq|y|$, so $x+y \geq 0$

$$
\begin{aligned}
{[x+y] } & =|x|-|y| \text { (using signed-magnitude rules) } \\
& =|x|+2^{n}-1-|y| \text { modulo } 2^{n}-1 \\
& =[x]+[y]
\end{aligned}
$$

2.26 Let the binary representation of $X$ be $x_{n-1} x_{n-2} \ldots x_{1} x_{0}$. Then we can write the binary representation of $Y$ as $x_{m} x_{m-1} \ldots x_{1 x_{0}}$, where $m=n-d$. Note that $x_{m-1}$ is the sign bit of $Y$. The value of $Y$ is

$$
Y=-2^{m-1} \cdot x_{m-1}+\sum_{i=0} x_{i} \cdot 2^{i}
$$

The value of $X$ is

$$
\begin{aligned}
X & =-2^{n-1} \cdot x_{n-1}+\sum_{i=0}^{n-2} x_{i} \cdot 2^{i} \\
& =-2^{n-1} \cdot x_{n-1}+Y+2^{m-1} \cdot x_{m-1}+\sum_{i=m-1}^{n-2} x_{i} \cdot 2^{i} \\
& =-2^{n-1} \cdot x_{n-1}+Y+2 \cdot 2^{m-1}+\sum x_{i} \cdot 2^{i}
\end{aligned}
$$

Case $1\left(x_{m-1}=0\right)$ In this case, $X=Y$ if and only if $-2^{n-1} \cdot x_{n-1}+\sum_{i=m}^{n-2} x_{i} \cdot 2^{i}=0$, which is true if and only if all of the discarded bits $\left(x_{m} \ldots x_{n-1}\right)$ are 0 , the same as $x_{m-1}$.
Case $2\left(x_{m-1}=1\right)$ In this case, $X=Y$ if and only if $-2^{n-1} \cdot x_{n-1}+2 \cdot 2^{m-1}+\sum_{i=m}^{n-2} x_{i} \cdot 2^{i}=0$, which is true if and only if all of the discarded bits $\left(x_{m} \ldots x_{n-1}\right)$ are 1 , the same as $x_{m-1}$.

2.27 If the radix point is considered to be just to the right of the leftmost bit, then the largest number is $1.11 \cdots 1$ and the 2 's complement of $D$ is obtained by subtracting it from 2 (singular possessive). Regardless of the position of the radix point, the 1 s ' complement is obtained by subtracting $D$ from the largest number, which has all 1 s (plural).

2.28 For the first part, note that the bit-by-bit complement of $Y$ may be written $\bar{Y}=2^{n}-1-Y$. Therefore, $Y=2^{n}-1-\bar{Y}$ and

$$
\begin{gathered}
X-Y=X-\left(2^{n}-1-\bar{Y}\right) \\
=X+\left(-2^{n}+1+\bar{Y}\right) \\
=\left(X+\bar{Y}+1-2^{n}\right)
\end{gathered}
$$

Next, consider the behavior of an $n$-bit adder for the operation $X+$ loverline $Y+1-2 n$. Suppose that no carry is produced:

$$
\begin{aligned}
\text { no carry } & \Rightarrow X+\bar{Y}+1<2^{n} \\
& \Rightarrow X<2^{n}-1-\bar{Y} \\
& \Rightarrow X<\bar{Y} \\
& \Rightarrow X-\bar{Y}<0 \\
& \Rightarrow \text { subtraction produces a borrow }
\end{aligned}
$$

Likewise, we can show

$$
\begin{aligned}
\text { carry } & \Rightarrow X+\bar{Y}+1 \geq 2^{n} \\
& \Rightarrow X \geq 2^{n}-1-\bar{Y} \\
& \Rightarrow X \geq Y \\
& \Rightarrow X-Y \geq 0 \\
& \Rightarrow \text { subtraction does not produce a borrow }
\end{aligned}
$$

$$
\begin{gathered}
B=-b_{n-1} \cdot 2^{n-1}+\sum_{i=0} b_{i} \cdot 2^{i} \\
2 B=-b_{n-1} \cdot 2^{n}+\sum_{i-n} b_{i} \cdot 2^{i+1}
\end{gathered}
$$

Case $1\left(b_{n-1}=0\right)$ First term is 0 , summation terms have shifted coefficients as specified. Overflow if $b_{n-2}=1$.
Case $2\left(b_{n-1}=1\right)$ Split first term into two halves; one half is cancelled by summation term $b_{n-2} \cdot 2^{n-1}$ if $b_{n-2}=1$. Remaining half and remaining summation terms have shifted coefficients as specified. Overflow if $b_{n-2}=0$.

2.33 With five states and eight possible 3-bit encodings, there are $\binom{8}{5}$ ways to choose the encodings, and 5 ! ways to assign encodings to states for each choice. Thus, the total is

$$
\binom{8}{5} \cdot 5!=\frac{8!}{5!\cdot 3!} \cdot 5!=8!/ 6=6720
$$

For seven states and eight possible 3-bit encodings, there are $\binom{8}{7}$ ways to choose the encodings, and 7! ways to assign encodings to states for each choice. Thus, the total is

$$
\binom{8}{7} \cdot 7!=\frac{8!}{7!\cdot 1!} \cdot 7!=8!/ 1=40320
$$

For eight states and eight possible 3-bit encodings, there is just one way to choose the encodings. Thus, the total is 8 ! or 40320 . This is the same answer as with seven states, because with each 7 -state encoding, there is exactly one leftover state which would be the eighth state in a corresponding 8 -state encoding.

2.34 Basically, your boss has forbidden the 111 encoding. Since there are 6 states and now only seven allowed 3-bit encodings, there are $\binom{7}{6}$ ways to choose the encodings, and $6!$ ways to assign encodings to states for each choice. Thus, the total is

$$
\binom{7}{6} \cdot 6!=\frac{7!}{6!\cdot 1!} \cdot 6!=7!/ 1=5040
$$

2.37 The manufacturer's code fails every 4th time, for a total of $2^{n-2}$ for an $n$-bit encoding disc. A standard binary code fails when the LSB changes from 1 to 0 , which changes the next bit (and possibly others), guaranteeing a problem. So, half the boundaries in a standard binary code are bad, a total of $2^{n-1}$ for an $n$-bit encoding disc. The manufacturer's code is only half as bad as a standard binary code.

2.38 Perhaps the designers were worried about what would happen if the aircraft changed altitude in the middle of a transmission. With the Gray code, the codings of "adjacent" alitudes (at 50-foot increments) differ in only one bit. An altitude change during transmission affects only one bit, and whether the changed bit or the original is transmitted, the resulting code represents an altitude within one step ( 50 feet) of the original. With a binary code, larger altitude errors could result, say if a plane changed from 12,800 feet $\left(000100000000_{2}\right)$ to 12,750 feet $\left(000011111111_{2}\right.$ ) in the middle of a transmission, possibly yielding a result of 25,500 feet (000111111111 2 ).

2.39 If a pair of bits $(H, L)$ represents the states of the high and low filaments in the bulb, a normal switch cycles through the sequence $(0,0)-(0,1)-(1,0)-(1,1)-(0,0)$, yielding the lighting sequence OFF-DIM-MEDIUM-BRIGHT-OFF. According to the binary sequence, the low filament is stressed twice during each complete cycle. Less stress would occur if the switch used a Gray-code sequence, $(0,0)-(0,1)-(1,1)-(1,0)-(0,0)$, yielding the lighting sequence OFF-DIM-BRIGHT-MEDIUM-OFF.

2.43 Think of it in terms of the string notation for subcubes. There are $\binom{n}{m}$ ways to pick the $m$ positions that contain 0 s and 1 s , and $2^{m}$ ways to assign 0 s and 1 s to a particular set of $m$ positions. So the total is $\binom{n}{m} \cdot 2^{m}$.

2.49 To get a minimum distance of 6 , we make a two-dimensional code using a distance- 3 Hamming code for the rows and a distance-2 even-parity check for the columns. Three possible two-dimensional matrices with a total of four information bits are summarized below.

| Row <br> data bits | Row <br> check bits | Column <br> data bits | Column <br> check bits | Matix size <br> (rows $\times$ columns) | Total bits |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 4 | 3 | 1 | 1 | $2 \times 7$ | 14 |
| 2 | 3 | 2 | 1 | $3 \times 5$ | 15 |
| 1 | 2 | 4 | 1 | $5 \times 3$ | 15 |

To obtain the minimum number of bits in a code word, we select the first case. The row code is a 7-bit Hamming code with four information bits and three check bits. Such a code is given in the first two columns of Table 1-14 in the text. The column code is an even-parity check with one information bit and one check bit, which is equivalent to duplicating the information bit. Thus, the two rows of each 14-bit two-dimensional code word are simply duplicates of a 7-bit code word from Table 1-14.
If the third case is selected, we get a code that is even easier to construct, though it has one more bit, a total of 15. The first column contains four information bits and an even-parity check bit. The second and third columns are copies of the first column.
