LEARNING OBJECTIVES

LO 2.1: Describe how genes and chromosomes provide our basic genetic endowment.

LO 2.2: Compare monozygotic twins with dizygotic twins.

LO 2.3: Describe how the sex of a child is determined.

LO 2.4: Explain the mechanisms by which genes transmit information.

LO 2.5: Describe the field of behavioral genetics.

LO 2.6: Describe the major inherited disorders.

LO 2.7: Describe the role of genetic counselors and differentiate between different forms of prenatal testing.

LO 2.8: Explain how the environment and genetics work together to determine human characteristics.

LO 2.9: Summarize the methods by which researchers study the interaction of genetic and environmental factors in development.

LO 2.10: Examine how genetics and the environment jointly influence physical traits, intelligence, and personality.

LO 2.11: Describe ways in which genes influence the environment.

LO 2.12: Describe the process of fertilization.

LO 2.13: Summarize the three stages of prenatal development.

LO 2.14: Describe major physical and ethical challenges that relate to pregnancy.

LO 2.15: Analyze threats to the fetal environment, and explain what can be done about them.

LO 2.16: Describe the normal process of labor.

LO 2.17: Describe the process of birth and analyze current approaches to childbirth.

LO 2.18: Recognize threats and complications that may accompany childbirth, and explain how they can be addressed.

LO 2.19: Describe the process of Cesarean delivery and explain why its use is increasing.

LO 2.20: Describe infant mortality rates and explain factors that affect those rates.

CHAPTER OUTLINE

I. Module 2.1: Earliest Development and the Foundations of Genetics

[Learning Objectives 2.1, 2.2, 2.3, 2.4, 2.5, 2.6, 2.7](#)

[Lecture Launchers 2.1, 2.5](#)

[Student Activity 2.1](#)

[MyDevelopmentLab Video: Genetic Counseling](#)

A. Genes and Chromosomes: The Code of Life

1. Humans begin life as a single cell.

- a. Our genetic code is stored and communicated in our **GENES**, *the basic units of genetic information*.
- b. Genes are composed of sequences of **DNA (deoxyribonucleic acid)**, *the substance that determines the nature of every cell in the body and how it will function*.
- c. Humans have over 25,000 genes.
- d. Genes are arranged in specific locations and in a specific order along 46 **CHROMOSOMES**, *rod-shaped portions of DNA that are organized in 23 pairs*.
 - (1) At fertilization, one pair of chromosomes (via the gametes) is provided by the mother and one is provided by the father.
 - (2) Sex cells contain half the number of chromosomes (not in pairs).
- e. Gametes (sperm and ova) are formed by a process called *meiosis*.
- f. A **ZYGOTE** is *one cell formed by fusion of the two gametes*.
- g. All other cells replicate the genetic code by a process called *mitosis*.
- h. There are tens of trillions of possible genetic combinations.

B. Multiple Births: Two—or More—for the Genetic Price of One

1. Less than 3 percent of all pregnancies produce twins; the odds are slimmer for 3 or more children.
2. **MONOZYGOTIC TWINS**, *who are genetically identical*, form when a cluster of cells in the ovum splits off within the first 2 weeks following fertilization.
3. **DIZYGOTIC TWINS**, *who are produced when two separate ova are fertilized by 2 separate sperm*, are no more genetically similar than any two siblings.
4. Other kinds of multiple births (triplets, quadruplets, etc.) can form from either mechanism.
5. Using fertility drugs increases the chances of having a multiple birth.
 - a. One in ten are dizygotic.
 - b. Older women are more likely to have multiple births.
6. Racial and ethnic differences affect the rate of multiple births.
 - a. White American: 1 out of 86 dizygotic.
 - b. African American: 1 out of 70 dizygotic.

C. Boy or Girl? Establishing the Sex of the Child

1. The 23rd chromosome determines the sex of the child.
 - a. Females are XX.
 - b. Males are XY.
 - c. The father's sperm determines the sex of the child.

D. The Basics of Genetics: The Mixing and Matching of Traits

1. An Austrian monk, Gregor Mendel (mid-1800s), discovered while working with peas that when two competing traits are present, only one can be expressed.
 - a. *The trait that is expressed when two competing traits are present is called the **DOMINANT TRAIT**.*

- b. *The trait that is present in the organism but not expressed is called the **RECESSIVE TRAIT**.*
 - c. **GENOTYPE** is the underlying combination of genetic material present (but not outwardly visible) in an organism.
 - d. **PHENOTYPE** is an observable trait, the trait that is actually seen.
 - e. Alleles are genes for traits that may take alternate forms.
 - (1) **HOMOZYGOUS** is inheriting from parents similar genes for a given trait.
 - (2) **HETEROZYGOUS** is inheriting from parents different forms of a gene for a given trait.
 - f. If a child receives a *recessive* allele from each parent, it will display the recessive characteristic.
2. Most traits are the result of **POLYGENIC INHERITANCE**, in which a combination of multiple gene pairs is responsible for the production of a particular trait.
- a. Some genes (such as those for blood type AB) are neither dominant nor recessive, but are a combination.
 - b. Some recessive genes are **X-LINKED GENES**, meaning *they are located on the X chromosome*.
 - (1) Males have a higher risk for a variety of X-linked disorders because they lack a second X chromosome to counteract the genetic information that produces the disorder.
 - (2) *Hemophilia* is a blood disorder produced by X-linked genes.
 - (3) Red-green color blindness is another.
- E. In 2001, molecular biologists succeeded in mapping the human genome—the specific sequence of genes on each chromosome.
- 1. The number of human genes has been revised downward from 100,000 to 25,000.
 - 2. Humans share 99.9 percent of the gene sequence.
 - 3. *The most recent approach to the study of the effects of heredity on behavior and development* is called **BEHAVIORAL GENETICS**.
 - a. This field merges psychology—the study of behavior—with genetics—the study of transmission of characteristics through heredity.
 - b. These researchers are learning how behavioral difficulties (such as schizophrenia) may have a genetic basis.
 - c. Researchers also seek to identify how genetic defects may be remedied.
- F. Inherited and Genetic Disorders: When Development Deviates from the Norm
- 1. Some genetic disorders are inherited (e.g., PKU).
 - 2. Some genetic disorders are the result of genes that become physically damaged.
 - a. Sometimes genes spontaneously change their form, a process called *spontaneous mutation*.
 - b. Certain environmental factors, such as exposure to X-rays, can produce malformed genetic material.
 - c. Some genetic disorders include:
 - (1) **DOWN SYNDROME** is a disorder produced by the presence of an extra chromosome on the 21st chromosome pair, once referred to as *mongolism*.
 - (2) **SICKLE-CELL ANEMIA** is a blood disorder that gets its name from the shape of the red blood cells in those who have it.
 - (3) **FRAGILE X SYNDROME** is a disorder produced by injury to a gene on the X chromosome, producing mild to moderate mental retardation.

- (4) **TAY-SACHS DISEASE** is an untreatable disorder that produces blindness and muscle degeneration prior to death.
 - (5) One male out of every 400 is born with **KLINEFELTER'S SYNDROME**, a disorder resulting from the presence of an extra X chromosome that produces underdeveloped genitals, extreme height, and enlarged breasts.
- G. Genetic Counseling: Predicting the Future from the Genes of the Present
1. **GENETIC COUNSELING** is the discipline that focuses on helping people deal with issues related to inherited disorders.
 - a. Genetic counselors use a variety of data.
 - b. They can take a thorough family history, seeking any familial incidence of birth defects.
 - c. The ages of the mother and father will be taken into account.
 - d. Blood, skin, and urine may be used to isolate and examine specific chromosomes.
 - e. Possible genetic defects can be identified by assembling a *karyotype*, a chart containing enlarged photos of each of the chromosomes.
 - f. Other tests take place once the woman is already pregnant.
 - (1) **ULTRASOUND SONOGRAPHY** is a process in which high-frequency sound waves scan the mother's womb to produce an image of the unborn baby whose size and shape can then be assessed.
 - (2) **CHORIONIC VILLUS SAMPLING (CVS)** is a test used to find genetic defects that involves taking samples of hair-like material that surrounds the embryo.
 - (3) **AMNIOCENTESIS** is the process of identifying genetic defects by examining a small sample of fetal cells drawn by a needle inserted into the amniotic fluid surrounding the unborn fetus.
 2. Screening for Future Problems
 - a. involves testing parents for the possibility that they will transmit diseases to children
 - b. presents a range of possibilities, rather than a simple "yes" or "no" answer
 - c. *Huntington's disease* and more than a thousand other disorders can be predicted based on genetic testing.
 - d. Prediction is complicated, because environment as well as genes determine a person's actual likelihood of becoming ill.
 - e. Researchers as well as medical practitioners are actively working to change flawed genes for intervention and manipulation.

II. Module 2.2: The Interaction of Heredity and Environment

[Learning Objectives 2.8, 2.9, 2.10, 2.11](#)

[Lecture Launchers 2.2, 2.3, 2.4](#)

[Student Activities 2.2, 2.3](#)

[MyDevelopmentLabVideo: Genetic Mechanisms and Behavioral Genetics](#)

- A. The Role of the Environment in Determining the Expression of Genes: From Genotypes to Phenotypes
1. An individual's **TEMPERAMENT**, the patterns of arousal and emotionality that represent consistent and enduring characteristics, may represent **MULTIFACTORIAL TRANSMISSION**, traits that are determined by a combination of both genetic and environmental factors in which a genotype provides a range within which a phenotype may be expressed.

2. Some genotypes are not as sensitive to the environment as others.
- B. Studying Development: How Much Is Nature? How Much Is Nurture?
1. The correct question is not whether behavior is caused by nature or nurture but *how much* by nature and *how much* by nurture.
 2. Nonhuman Studies: Controlling Both Genetics and Environment
 - a. Scientists put laboratory animals bred to share genetic backgrounds in different environments to explore the effects of these environments.
 - b. Conversely, they use genetically different animals in similar environments to determine the role of genetics.
 3. Contrasting Relatedness and Behavior: Adoption, Twin, and Family Studies
 - a. Scientists use human twins to study the effects of genes and the environment.
 - b. Differences between monozygotic twins separated at birth are most likely—but not always—due to different environments.
 - c. If monozygotic twins are more similar than dizygotic twins on a particular trait, we can assume that genetics plays a role in the expression of that trait.
 - d. People who are unrelated but share the same environment also tell us about environmental influences.
 - e. Researchers also study biological parents and their children versus adoptive parents and their children to see the effects of heredity versus environment.
 - f. Bottom line: virtually all traits, characteristics, and behaviors are the joint result of the combination and interaction of nature and nurture.
 4. The more genetically similar two people are, the more likely they are to share physical characteristics (e.g., height, weight).
- C. Genetics play a significant role in intelligence; however, the environment is also a major factor.
1. Increasing evidence supports the conclusion that at least some personality traits have a genetic component.
 - a. *Neuroticism* refers to the degree of moodiness, touchiness, or sensitivity an individual characteristically displays.
 - b. *Extroversion* is the degree to which a person seeks to be with others, to behave in an outgoing manner, and generally to be sociable.
 - c. Certain traits reflect the contribution of genetics more than others.
 - (1) novelty-seeking tendencies
 - (2) social potency
 - (3) traditionalism
 - d. Political attitudes, religious interests and values, and even attitudes toward human sexuality seem to have genetic components.
 - e. Environmental factors such as parental nurturance also impact traits.
 - (1) parents' attitudes and encouragement of high/low activity levels
 - (2) Cultural contexts for parental attitudes shape differences in such traits.
- D. Can Genes Influence the Environment?
1. Children's genetic predispositions might influence their environment (Scarr).
 - a. Children focus on aspects of their environment that connect with their genetically determined abilities, and attend less to environmental features that are less compatible with genetically determined traits.
 - b. The gene-environment influence can be more passive and less direct in other cases.
 - c. The genetically determined temperament of a child can evoke certain influences from the environment or parents.

2. The relative influence of genes and environmental factors can shift over the course of the lifespan.

III. Module 2.3: Prenatal Growth and Birth

[Learning Objectives 2.12, 2.13, 2.14, 2.15, 2.16, 2.17, 2.18, 2.19, 2.20](#)

[Lecture Launchers 2.6, 2.7, 2.8](#)

[Student Activities 2.4, 2.5, 2.6](#)

[MyDevelopmentLab Video: Period of the Zygote](#)

[MyDevelopmentLab Video: Labor](#)

[MyDevelopmentLab Video: Premature Births and the Neonatal Intensive Care Unit](#)

- A. Fertilization: The Moment of Conception
 1. **FERTILIZATION** is the process by which a sperm and an ovum—the male and female gametes—join to form a single new cell.
- B. The Stages of the Prenatal Period: The Onset of Development
 1. The **GERMINAL STAGE** is the first and shortest stage of prenatal development, which takes place during the first 2 weeks following conception.
 - a. It is characterized by methodical cell division and the attachment of the organism (*blastocyst*) to the wall of the uterus.
 - b. The baby is called a *zygote* at this stage.
 - c. The cells become specialized with some forming a protective layer around the zygote, while others create:
 - (1) **PLACENTA**, the conduit between the mother and fetus, providing nourishment and oxygen via the umbilical cord.
 2. The second stage is called the **EMBRYONIC STAGE**, the period from 2 to 8 weeks following fertilization during which significant growth occurs in the major organs and body systems.
 - a. At this point, the child is called an *embryo*.
 - b. By the end of this phase, the embryo is about an inch in length, with a tail-like structure and the beginnings of eyes, lips, teeth, arms, and legs. The head and brain begin rapid development.
 - c. The developing child is now composed of three layers.
 - (1) The *ectoderm* is the outer layer forming the skin, hair, teeth, sense organs, brain, and spinal cord.
 - (2) The *endoderm* is the inner layer producing the digestive system, liver, pancreas, and respiratory system.
 - (3) The *mesoderm* is sandwiched between the inner and outer layers and forms the muscles, bones, blood, and circulatory system.
 3. The **FETAL STAGE** begins about 8 weeks after conception and continues until birth.
 - a. The developing child from 8 weeks after conception until birth is called a **FETUS**.
 - b. The fetus dramatically increases in size and weight.
 - c. Organs become more differentiated and operational.
 - d. By three months, the fetus swallows and urinates.
 - e. By four months, the mother will be able to feel her fetus move.
 - f. Brain growth continues as the left and right hemispheres of the brain develop and neurons become coated with an insulation called *myelin*.
 - g. Hormones begin to flow differently to male and female fetuses.
- C. Pregnancy Problems: Giving Nature a Boost
 1. Fifteen percent of couples suffer from **INFERTILITY**, the inability to conceive after twelve to eighteen months of trying to become pregnant.

2. Infertility is produced by several causes.
 - a. the age of the parents
 - b. previous use of birth control pills, illicit drugs or cigarettes, or STDs
 - c. men who have an abnormally low sperm count
 - d. the woman's *mother* taking certain drugs during pregnancy
 - e. The most common cause of infertility is failure to release an egg through ovulation—possibly caused by hormonal imbalance, damage to the fallopian tubes or uterus, or stress.
 3. There are several approaches to conception in these cases.
 - a. **ARTIFICIAL INSEMINATION** is a *process of fertilization in which a man's sperm is placed directly into a woman's vagina by a physician.*
 - b. **IN VITRO FERTILIZATION (IVF)** is a *procedure in which a woman's ova are removed from her ovaries and a man's sperm are used to fertilize the ova in a laboratory.*
 - c. A **SURROGATE MOTHER** is a *woman who agrees to carry the child to term; may be used in cases where the mother is unable to conceive.*
 4. Ethical Issues
 - a. Ethical and legal issues as well as emotional concerns are present, and may result in the rights of the mother, the father, the surrogate mother, and ultimately the child being in conflict.
 - b. Sex-selection techniques are even more troubling, and questions arise about intervening in the reproductive process to obtain a favored sex or other characteristics.
 - c. Evidence suggests that the quality of parenting in families who have used artificial means to conception may even be superior to the parenting in families with naturally conceived children.
 - d. The psychological adjustment of children conceived artificially is no different than that of children conceived using natural techniques.
 5. Miscarriage and Abortion
 - a. A *miscarriage*—known as spontaneous abortion—occurs when pregnancy ends before the developing child is able to survive outside the womb.
 - (1) Fifteen to twenty percent of all pregnancies end in miscarriage.
 - (2) In many cases, the woman is not even aware that she was pregnant.
 - (3) Typically, miscarriages are attributable to some sort of genetic abnormality.
 - b. *Abortion* is the voluntary termination of a pregnancy.
- D. The Prenatal Environment: Threats to Development
1. Certain aspects of mothers' and fathers' behavior, both before and after conception, can produce lifelong consequences for the child.
 2. Some of the most profound consequences are brought about by a **TERATOGEN**, *an environmental agent such as a virus, chemical, or other factor that produces a birth defect.*
 - a. Timing and quantity of exposure to teratogens are crucial factors in assessing risk.
 - b. At some phases of prenatal development, a teratogen may have minimal impact; at other periods, consequences can be severe.
 - (1) A mother's diet clearly plays an important role in bolstering the development of the fetus.
 - (2) Research shows that mothers over 30 and adolescent mothers are at greater risk for a variety of pregnancy and birth complications including premature birth.

- (3) About 90 percent of women's eggs are no longer normal at age 42. Older women (relative to younger women) are at risk for having children with:
 - (a) premature birth
 - (b) low birth weight
 - (c) Down syndrome
 - (4) *Rubella* (German measles) prior to the eleventh week can cause blindness, deafness, heart defects, or brain damage.
 - (5) *Chicken pox* and *mumps* may cause birth defects and miscarriage, respectively.
 - (6) *Syphilis* and *gonorrhea* can be transmitted to the child.
 - (7) Babies may acquire AIDS (*acquired immune deficiency syndrome*) from their mothers through the placenta.
 - c. A mother's use of legal and illegal drugs poses serious risks to the unborn child.
 - (1) Aspirin can lead to bleeding.
 - (2) *DES (diethylstilbestrol)* later caused cervical and vaginal cancer in daughters.
 - (3) Exposure to birth control or fertility pills in utero can affect brain structures in the fetus.
 - d. Both alcohol and cigarettes can disrupt the development of the fetus.
 - (1) **FETAL ALCOHOL SPECTRUM DISORDER (FASD)** is *a disorder caused by the pregnant mother consuming substantial quantities of alcohol during pregnancy, potentially resulting in mental retardation, delayed growth, and facial deformities.*
 - (2) Even smaller amounts of alcohol can produce **FETAL ALCOHOL EFFECTS (FAE)**, *a condition in which children display some, although not all, of the problems of FAS due to their mothers' consumption of alcohol during pregnancy.*
 - (3) Just two drinks a day has been associated with lower intelligence.
 - (4) Smoking reduces the oxygen content and increase carbon monoxide.
 - (a) Babies can miscarry or are born with abnormally low birth weight.
 - (b) Babies born to smokers are shorter and may be 50 percent more likely to have mental retardation.
 - e. Fathers can affect the prenatal environment.
 - (1) Secondhand smoke can affect the mother's health.
 - (2) Alcohol and illegal drugs can lead to chromosomal damage at conception.
 - (3) Stress may produce an unhealthy environment for the mother.
 - (4) Sperm damage may result from a father's exposure to environmental toxins in the workplace.
- E. The Process of Birth
- 1. About 266 days after conception, a protein called *corticotropin-releasing hormone (CRH)* triggers the process of birth.
 - a. The hormone oxytocin is released from mother's pituitary.
 - b. *Braxton-Hicks contractions* have been occurring since the fourth month.
 - c. Contractions force the head of the fetus against the *cervix*.
 - d. Labor proceeds in 3 stages.
 - (1) The *first stage* is the longest.

- (a) Uterine contractions occur every 8–10 minutes and last about 30 seconds.
 - (b) Contractions increase to their greatest intensity, a period known as *transition*.
 - (c) The mother’s cervix fully opens.
 - (d) For first babies, this stage can last 16–24 hours (this varies widely).
 - (e) Subsequent children involve shorter periods of labor.
 - (2) During the *second stage of labor*, the baby’s head moves through the birth canal.
 - (a) This stage typically lasts 90 minutes.
 - (b) After each contraction, the baby’s head emerges more and increases the vaginal opening.
 - (c) An **EPISIOTOMY** is an *incision sometimes made to increase the size of the opening of the vagina to allow the baby to pass*.
 - (d) This stage ends when the baby is born.
 - (3) The *third stage of labor* occurs when the child’s umbilical cord and placenta are expelled.
 - (a) This is the shortest stage.
 - (b) It lasts only minutes.
 - (4) Cultural perspectives color the way that people in a given society view the experience of childbirth.
- F. Approaches to Childbirth: Where Medicine and Attitudes Meet
1. There are a variety of choices for how to give birth and no research proves that one method is more effective than another.
 2. There are several alternative birthing procedures.
 - a. *Lamaze birthing techniques* (Dr. Fernand Lamaze)
 - (1) The goal is to learn how to deal positively with pain and to relax at the onset of a contraction.
 - (2) Low-income and minority groups may not take advantage of these *natural childbirth techniques*.
 - b. *Bradley Method*
 - (1) known as “husband-coached childbirth”
 - (2) principle: childbirth should be as natural as possible
 - (3) involves no medication or medical interventions
 - c. *Hypnobirthing*
 - (1) involves a self-hypnosis during delivery
 - (2) produces peace and calm, thereby reducing pain
 - d. *Water birthing*
 3. Childbirth Attendants: Who Delivers?
 - a. Birthing centers are homelike, and less foreboding or stressful than a hospital.
 - b. The use of birthing centers is becoming increasingly common.
 - c. Some parents use a *midwife*, a nurse specializing in childbirth, instead of an *obstetrician*, a physician who specializes in childbirth.
 - d. Although relatively rare in the U.S., midwives deliver some 80 percent of babies in other parts of the world.
 4. Use of Anesthesia and Pain-Reducing Drugs
 - a. The use of medication during childbirth has benefits and disadvantages.

- b. Eighty percent of women receive some form of pain medication during childbirth.
- c. One-third of women receive an *epidural anesthesia*, which produces numbness from the waist down.
 - (1) A newer form is known as *walking epidural* or *dual spinal-epidural*, which use smaller needles and a system of delivering continuous doses of anesthetic, allowing women to move about more freely during labor.

G. Birth Complications

1. Preterm Infants: Too Soon, Too Small
2. **PRETERM INFANTS**, *who are born prior to 37 weeks' gestation (also known as premature infants)*, are at high risk for illness and death.
 - a. The main factor in determining the extent of danger is the child's weight at birth.
 - (1) The average newborn weighs 3,400 grams (7 1/2 pounds).
 - (2) **LOW-BIRTHWEIGHT INFANTS** *weigh less than 2,500 grams (5 1/2 pounds)*.
 - (3) Although only 7 percent of all newborns in the U.S. are low-birthweight, they account for the majority of newborn deaths.
 - (4) **SMALL-FOR-GESTATIONAL-AGE INFANTS**, *because of delayed fetal growth, weigh 90 percent or less of the average weight of infants of the same gestational age*.
 - b. Premature infants are susceptible to *respiratory distress syndrome (RDS)* because of poorly developed lungs.
 - c. Low-birthweight infants are put in *incubators*, enclosures in which oxygen and temperature are controlled.
 - (1) easily chilled, susceptible to infection, sensitive to environment
 - d. Preterm infants develop more slowly than infants born full-term.
 - (1) Sixty percent eventually develop normally.
 - (2) Thirty-eight percent have mild problems (learning disabilities, low IQ).
3. **VERY-LOW-BIRTHWEIGHT INFANTS** *weigh less than 1,250 grams (2 1/4 pounds) or, regardless of weight, have been in the womb less than 30 weeks and are in grave danger because of the immaturity of their organ systems*.
 - a. Medical advances have pushed the **AGE OF VIABILITY**, *or point at which an infant can survive a premature birth*, to about 22 weeks.
 - b. A baby born earlier than 25 weeks has less than a 50/50 chance of survival.
 - c. Costs of keeping very-low-birthweight infants alive are enormous.
 - d. Research shows that children who receive more responsive, stimulating, and organized care are apt to show more positive outcomes than children whose care was not as good.
4. What Causes Preterm and Low-Birthweight Deliveries?
 - a. fifty percent are unknown causes
 - b. multiple births
 - c. young mothers (under age 15)
 - d. too closely spaced births
 - e. general health and nutrition of mother
 - f. African-American mothers have double the number of low-birthweight babies that Caucasian mothers do.
5. Postmature Babies: Too Late, Too Large

- a. **POSTMATURE INFANTS**, *those still unborn 2 weeks after the mother's due date, face several risks.*
 - (1) Blood supply to the baby's brain may be decreased and cause brain damage.
 - (2) Labor and delivery become more difficult.
- H. Cesarean Delivery: Intervening in the Process of Birth
 - 1. Over a million mothers in the U.S. today have a **CESAREAN DELIVERY**, *where the baby is surgically removed from the uterus, rather than traveling through the birth canal.*
 - 2. Several types of difficulties can lead to Cesarean delivery.
 - a. Fetal distress is the most frequent reason for a Cesarean section.
 - b. used for *breech position*, where the baby is positioned feet first in the birth canal
 - c. used for *transverse position*, in which the baby lies crosswise in the uterus
 - d. when the baby's head is large
 - e. Mothers over age 40 are more likely to have Cesarean deliveries than younger ones.
 - 3. Routine use of **FETAL MONITORS**, *devices that measure the baby's heartbeat during labor*, have contributed to soaring rates of Cesarean deliveries—up 500 percent from 1970s. Their use has evoked several criticisms.
 - a. There is no association between Cesarean delivery and successful birth consequences.
 - b. It involves major surgery and a long recovery for the mother.
 - c. There is a risk of infection to the mother.
 - d. Easy birth may deter release of certain stress hormones, such as catecholamines, which help prepare the infant to deal with stress outside the womb.
- I. Mortality and Stillbirth: The Tragedy of Premature Death
 - 1. **STILLBIRTH** is *the delivery of a child who is not alive and occurs in less than 1 delivery in 100.*
 - 2. The rate of stillbirths has been declining since 1960s.
 - 3. **INFANT MORTALITY** is defined as *death within the first year of life.*
 - a. The overall rate is 7.0 deaths per 1,000 live births.
 - b. Parents grieve in the same manner as if an older loved one had died.
 - c. Depression is a common aftermath.

LECTURE LAUNCHERS

Lecture Launcher 2.1: The Epidemic That Wasn't—Crack Babies

The findings of Barry Lester's longitudinal research on crack babies are discussed in this *New York Times* article. Although there are significant differences in IQ between those exposed to crack prenatally and their non-exposed counterparts, the differences are smaller than even Lester expected and likely not clinically significant. Students can be divided into groups to do their own research on a particular teratogen and then they can report out.

http://www.nytimes.com/2009/01/27/health/27coca.html?pagewanted=all&_r=0

Lecture Launcher 2.2: Fertility

Traditionally, estimates of women's fertility ranged anywhere from two days to ten days a month. However, a study by the National Institute of Environmental Health Sciences in Research Park, NC, published in the *New England Journal of Medicine*, found that women are fertile for five days before ovulation as well as on the day of ovulation. Researchers were surprised to find that having sex just one day after ovulation will not result in a pregnancy. Kits are available which tell when a woman is ovulating. (For couples wanting to avoid pregnancy, these researchers suggest abstaining from sex, or using birth control, during this six-day period.)

According to the study, the probability of conception ranges from 10% when intercourse occurs five days before ovulation to 33% when it happens on the day of ovulation. Daily intercourse results in the highest chance of pregnancy, 37%. The study had some other findings: There is no evidence that the timing of intercourse influences whether the baby will be a boy or a girl. Also, there is no sign that aging sperm is more likely to produce babies with defects, although the study was too small to support this conclusively.

On average, couples have a 20% chance of getting a viable pregnancy each month. However, according to Dr. Allen Wilcox, who conducted the study, "even couples who are very fertile are not fertile in every cycle. We don't understand why that is." Results from another study show that women who drink three or more cups of coffee a day reduce their chances of conception by 26 percent. It is believed that caffeine disrupts the menstrual cycle and may lead to early pregnancy loss.

Wilcox, A. J., Weinberg, C. R., & Baird, D. D. (December 7, 1995). Timing of sexual intercourse in relation to ovulation. Effects on the probability of conception, survival of the pregnancy, and sex of the baby. *New England Journal of Medicine*, 333(23), 1517–1521.

Wilcox, A. J., Baird, D. D., Dunson, D. B., McConaughey, D. R., Kesner, J. S., & Weinberg, C. R. (2004). On the frequency of intercourse around ovulation: Evidence for biological influences. *Human Reproduction*, 19(7), 1539–1543.

Wilcox, A. J. (2010). *Fertility and pregnancy: An epidemiologic perspective*. Oxford University Press.

Lecture Launcher 2.3: Infertility

Contrary to popular opinion, infertility rates are not on the rise. In 1965, the U.S. infertility rate was 13.3%; in 1988 it was 13.7%. However, estimates are that one-sixth of all couples who try to conceive are sterile or infertile. Jewelewicz (1989) cites several reasons for this:

The rise in sexually transmitted diseases, women entering the workforce and being exposed to occupational hazards that affect their fertility, and the possibility of being exposed to more environmental toxins, are all reasons hypothesized for increased infertility.

Women are delaying childbirth and increased age is related to decreased fertility.

Oral contraceptives and use of an IUD may account for some cases of infertility.

Because of second marriages, some couples seek to reverse previous surgical sterilizations.

More techniques are available and written about in the media so couples are more aware of help for infertility.

The top five procedures for fertilization include:

- in vitro fertilization (IVF)
- gamete intrafallopian transfers (GIFT)
- intrauterine insemination (IUI)
- zygote intrafallopian transfer (ZIFT)
- intracytoplasmic sperm injection (ICSI)

There are some pros and cons about the new reproductive technologies. For example, before the 1970s, only *donor insemination*—injection of sperm from an anonymous man into a woman—was available for infertile women. Today, *in vitro fertilization* is a common choice where hormones are used to stimulate the production of several ova, which are removed. The eggs are placed in a dish of nutrients, sperm are added, and then the fertilized eggs are injected into the mother. Ova can be screened for genetic defects and fertilized ova can also be frozen for use in the future. Sperm can also be frozen. Few states have legal guidelines for these procedures. Consequently, problems that might arise include:

- genetic defects
- sexually transmitted diseases
- poor records of donor characteristics
- possibility that children from the same donor may grow up together and marry
- use of genetic selection for the “perfect child”
- use of “surrogate mothers”

Use **Handout 2-1** to review some reasons for infertility and various solutions.

Lecture Launcher 2.4: In Vitro Fertilization and Multiple Births

In 2009, a single mother named Nayda Suleman gained national attention when she gave birth to octuplets. Dubbed the “Octomom” by the press, Suleman already had six children, with all of her pregnancies being the result of *in vitro* fertilization, which can carry the consequence of multiple births. Several popular reality television programs, such as “Kate Plus 8,” have also made celebrities out of parents who have had multiple birth pregnancies using assisted reproduction technologies. All of this attention has caused some people to ask whether children from multiple birth pregnancies are at risk for developmental problems.

Concern over developmental problems with multiple births focuses on two distinct issues. First, multiple birth pregnancies are associated with premature births, lower birth weights, and other complications from having multiple fetuses in the womb at once. Because abnormal *in utero* development can have a long lasting impact on brain development, multiple birth pregnancies have the potential to cause permanent cognitive disabilities.

The other issue of concern regarding the development of children in multiple birth families is whether the strain that so many children at the same age puts on a family interferes with the parents' abilities to provide a healthy environment. For example, parents may have little time and attention to devote to each child. Furthermore, the financial burdens may cause children to go without toys and other items.

Introduce the concept of multiple births to students, along with their increased prevalence when in vitro fertilization is used. Ask students to discuss whether they believe children from large, multiple birth pregnancies are likely to have their development affected in a negative way. Should fertility doctors be banned from implanting more than one or two embryos at a time? Do they feel that children in large families from single births are also at risk? To extend the activity, ask students to respond to the writing prompt below.

Lecture Launcher 2.5: My Mother, Myself

Many people feel that their mothers are “a part of them.” Recent findings suggest that there may be considerable truth to that phrase.

Many adults apparently still have cells in their bodies that they picked up from their mothers during the gestation period. Similarly, many mothers still have cells in their bodies that came from their own children during pregnancy. Technically speaking, these “guest cells” are actually the product of stem cells that got planted in the “host’s” body and started reproducing decades later. And, technically speaking, there aren’t too many of them. Some estimates put the number of foreign cells at less than one in a million, a comforting thought for anyone conjuring up images of parasitic offspring or alien-like entities living happily rent-free.

The meaning of these *microchimeras* is less clear. There is some evidence that these cells might contribute to autoimmune diseases, although there is also speculation that these cells might confer a health benefit. Because this area of study is relatively young, there remain more questions than answers (such as, what about women who have cells from both their mothers and their own offspring?). It’s comforting to know, though, that in some small way a parent is always with us.

Ritter, M. (2003, May 9). Moms, you’ve got a little of your kids inside you. *Austin American-Statesman*, A1, A16.

Lecture Launcher 2.6: Childbirth Options

Methods of childbirth have changed dramatically during the past 50 years. Most current methods are based on the pioneering work of Grantly Dick-Read in England and Ferdinand Lamaze in France. In 1944, Dick-Read proposed that fear is the major cause of most of the pain of childbirth. He proposed the concept of *natural childbirth* and developed a method of teaching women about reproduction, pregnancy, delivery, and exercises in breathing, relaxation, and fitness. Lamaze, in the 1950s, developed a method called *prepared childbirth* where expectant mothers are taught to breathe and concentrate on sensations other than contractions. This is facilitated by a “coach,” usually the father, who attends classes with her and helps time her breathing. Fathers then became a part of the childbirth process, and by the 1970s hospitals were beginning to allow them to go into the delivery room to assist. Now, most fathers elect to participate in the birth of their children.

Although the vast majority of all babies born in the United States are born in hospitals, some women elect to have their babies at home with the services of either a physician who specializes in home births or a midwife, a specially trained nurse. These options should only be used by women whose pregnancies are low risk. Hospitals responded to the home-birth movement by offering birthing centers, rooming-in facilities so mothers and babies are together all day, and sibling visitations. Some women also enlist the services of a doula, a non-medical professional who can provide support during labor (and sometimes afterwards, during the baby's first few days of life).

Lecture Launcher 2.7: Are There Too Many Cesarean Section Deliveries?

More Cesarean section deliveries (c-sections) are performed in the United States than in any other industrialized nation. C-section rates have risen 50% since 1979. Reasons for Cesarean delivery include: labor is progressing poorly; the mother has had a previous c-section (although many women can successfully deliver vaginally after a previous c-section); the baby is in the breech or transverse position; the mother has an active case of genital herpes; to avert potential malpractice suits. Some critics argue that the use of a fetal monitor has increased the incidence of c-sections. Babies born by c-section miss out on the stress hormones released during birth (*catecholamines*). These hormones are believed to help in the post-birth breathing process. The effects on mothers are a result of the major abdominal surgery involved, which is associated with a longer hospital stay, longer recovery, higher rates of postpartum depression, and a greater risk of infection.

Lecture Launcher 2.8: Benefits of Massaging Preterm Babies

Post-maturity syndrome occurs when the placenta reaches its peak before term and calcifies to such an extent that the fetus is not able to be adequately nourished. Babies delivered under these conditions may have dry, peeling skin, appear emaciated, and often spend time in a neonatal intensive care unit (NICU). This can be a traumatic experience...especially for a tiny person who's just entered the world and doesn't know many people yet! Tiffany Field and her colleagues recognized that fetuses knew how to suck their thumbs, so they gave pacifiers to newborns as they were being given heel-sticks (a way to draw blood for testing). The researchers gave one group the pacifiers during this procedure and the other group (the controls) did not receive them. Those in the pacifier groups cried less, showed slower breathing, and had a slower heart rate. In another study they gave pacifiers to babies who were being tube fed. These babies were weaned from tube feeding earlier, were easier to bottle feed, gained more weight per day, and were discharged from the hospital sooner.

In her infant massage work, Field built on the technique of an abdomen massage that was being used by nurses in another part of the country. Field and her colleagues gave whole body massages to preterm infants, being careful that they were Swedish massages because they entailed deep pressure. (Light pressure is likely to be perceived as an aversive tickle. This may explain why other research that had examined the effects of infant massage yielded mixed results: Some studies found weight gain and others did not.) Field and colleagues randomly assigned some babies to the experimental groups that received 45 minutes of massage a day for a 10-day period in 15-minute sessions at the beginning of three consecutive hours. The others did not receive the massages. Following the 10-day period, the massaged babies showed fewer stress responses (they were less likely to clench their fists and less likely to show grimacing). They scored better on the Brazelton Newborn Behavior Assessment Scale and most incredibly, they gained more weight (despite being fed the same number of calories as those in the control group).

This is a great example of applied research that got a lot of attention—after all, think of the money that was saved by being able to send these babies home sooner!

STUDENT ACTIVITIES

Student Activity 2.1: The Nature-Nurture Issue: Lessons from the Pillsbury Doughboy

David B. Miller uses a cooking metaphor to describe the intricate interactions between genetics/biology (nature) and the environment/learning (nurture). In his metaphor, flour represents genes. He takes four different food items, which represent four different developmental outcomes that all use flour as a base but that have other ingredients that interact with the flour in unique ways.

1. FLOUR + SALT + WATER + FRIED IN SHORTENING = FLOUR TORTILLA
2. FLOUR + SALT + WATER + BAKED WITHOUT SHORTENING = MATZO
3. FLOUR + SALT + WATER + YEAST + BAKING = BREAD
4. FLOUR + SALT + BUTTER + COCOA + SUGAR + BAKING = BROWNIE

Depending on how adventuresome you feel, you can demonstrate this lesson in a variety of ways. You can bring in an example of each ingredient (e.g., a bag of flour, a box of salt, some water, a can of shortening, a packet of yeast, some butter, a can of cocoa, a bag of sugar, and perhaps a toy oven) and use them as props to create the “developed” results (e.g., tortilla, matzo, bread, and brownie). You could actually mix some of the ingredients and assign students to go home and finish them. Finally, you could assign small groups ahead of time to make the various products and bring them to class; each group must explain how their ingredients relate to real-world human development (i.e., flour = genes, salt = culture, water = health, baking/frying = home environment). Each group must explain their results. Miller suggests that the metaphor of tortilla versus matzo shows how similar ingredients (i.e., shared genes of identical twins) can yield different developmental outcomes (i.e., different personalities, intelligence, etc.) due to different environments (i.e., baking versus frying).

Miller, D. B. (1996). The nature-nurture issue: Lessons from the Pillsbury Doughboy. In Ware, M. E. and Johnson, D. E. (Eds.), *Handbook of demonstrations and activities in the teaching of psychology, Volume II: Physiological-comparative, perception, learning, cognitive, and developmental*. Mahwah, NJ: Lawrence Erlbaum Associates, pp. 201–203.

Student Activity 2.2: Conception and Pregnancy

Use **Handout 2-2** for this assignment. Distribute the handout before you discuss conception and pregnancy. Tell students that some of the answers are in Chapter 2 and some they will have to find on their own using other sources.

This handout can be used as an assignment to be completed before your lectures on conception and pregnancy or as a review. The answers are:

Conception

1. ovary → fallopian tube → uterus → uterine wall (fertilized) or vagina (unfertilized)
2. penis → vagina → uterus → fallopian tube → egg (ovum)
3. possible answers include blocked/damaged fallopian tubes, abnormal ovulation, pelvic inflammatory disease (PID), endometriosis, damaged ovaries, hostile cervical mucus, fibroid tumor
4. possible answers include low sperm count, dilated veins around testicle, damaged sperm ducts, hormone deficiency, sperm antibodies
5. possible answers include surgery, in vitro fertilization, hormone therapy, antibiotics, artificial insemination

Pregnancy

1. possible answers include cessation of menses, breast tenderness, nausea
2. Stage 1: Germinal lasts two weeks (from conception till week 2), the cells divide and attach to the uterine wall, the baby is called a “zygote”
Stage 2: Embryonic stage lasts 6 weeks (from week 2 until week 8), the cell layers (endoderm, ectoderm, mesoderm) form, the baby is called an “embryo”
Stage 3: Fetal stage lasts 7 months (from week 8 until birth), all the child’s systems are developing rapidly, the child is called a “fetus”
3. possible answers are see an obstetrician/midwife, eat a healthy diet including calcium and multivitamin and mineral supplements, abstain from caffeine, alcohol, nicotine, and unnecessary drugs, get plenty of rest, avoid X-rays, exercise moderately
4. amniocentesis—fetal cells are taken via a needle from amniotic fluid
chorionic villus sampling (CVS)—samples of hairlike material taken from embryo
ultrasound sonography—high frequency sound waves produce an image of baby
5. possible answers include alcohol, nicotine, X-rays, prescription drugs such as Thalidomide, illicit drugs such as cocaine and marijuana, illnesses of the mother such as rubella, influenza, and AIDS

Student Activity 2.3: Buying Eggs or Finding a Sperm Donor or Surrogate on the Internet

Ask students to use the Internet to explore their options for becoming parents. Have them note the prices paid for eggs, sperm, etc., by visiting several sites that offer reproductive help or reproductive services.

Pose the following question: How far is too far to go? Ask students what they would do if they wanted to have a child, but could not. (Consider the following possibilities: they found out that they are infertile; they have a genetic condition that has a chance of being passed to their offspring.) You might also share **Handouts 2-3** and **2-4** in this context. Handout 2-3 lists some dominant and recessive characteristics that sometimes influence people’s wishes for a “designer baby.” Handout 2-4 lists some common teratogens that can affect prenatal development.

Student Activity 2.4: Infant Reflexes

If possible, invite several parents to bring in their babies to illustrate reflexes in the newborn. Distribute copies of **Handout 2-5**, which lists both survival and primitive infant reflexes. Your students might try to guess the survival value of each reflex.

Student Activity 2.5: Critical Thinking Exercises

1. Get copies of Darcy Frey’s article in the *New York Times Magazine* titled “Does Anyone Here Think This Baby Can Live?” (see **Supplemental Reading** for the complete reference; the article is also available here: <http://www.nytimes.com/1995/07/09/magazine/does-anyone-here-think-tnis-baby-can-live.html?pagewanted=all>). Have your students read the article and write an essay considering the following questions.
 - What are some ethical considerations related to the provision of intensive medical care to very-low-birthweight babies?
 - Do you think such interventions should be routine practice? Why or why not?

2. Have students investigate the cost of childbirth in their city. These costs should include prenatal care, the hospital/doctor or midwife charges, and costs of items for the baby, such as clothing, well-baby checkups, and furniture.

Student Activity 2.6: Reflective Journal Exercises

Ask students to interview a woman about her pregnancy; ideally a family member, but any close friend, colleague, or willing acquaintance will do. Distribute **Handout 2-6** as a starting point for their task, and emphasize that the interviewee's responses should form the basis for the student's own reflections.

Handout 2-7 offers some prompts to reflect on the process of childbirth and the first few days of life. Ask students to use these questions to construct a Reflective Journal entry.

MULTIMEDIA IDEAS

MyDevelopmentLab Video Series + Discussion Questions

The **MyDevelopmentLab Video Series** engages students and brings to life a wide range of topics spanning prenatal development through the end of the lifespan. New international videos shot on location allow students to observe similarities and differences in human development across various cultures.

Video: Genetic Counseling

Discussion Questions

1. What are your thoughts on genetic counseling after viewing this clip? Did viewing this video change your opinion on the topic?
2. Would you, or did you, seek genetic counseling during your pregnancy? Why or why not? Would you recommend it to others?
3. The professional interviewed lists several reasons why individuals might consider genetic counseling. List and describe at least three.

Video: Period of the Zygote

Discussion Questions

1. Explain the steps involved in the process of fertilization.
2. What is the correct sequence of stages that take place during the zygotic period, and what is the timeframe for each?
3. Sketch the location of the female reproductive organs, noting key areas involved in zygotic development.

Video: Genetic Mechanisms and Behavioral Genetics

Discussion Questions

1. Review the process of genetic transmission, focusing on how parental chromosomes contribute to the formation of a new life.
2. Explain how family studies, adoption studies, and twin studies provide key information to researchers studying behavioral genetics.
3. Comment on the specific findings of the studies described by the researcher interviewed in the video. Which outcomes did you find most interesting, unusual, or unexpected?

Video: Labor

Discussion Questions

1. Although the narrator tells us that the trigger for labor is still a mystery, he provides a few possibilities. Explain those possibilities.
2. List at least three signals a woman may experience to let her know she is about to begin labor.
3. Describe the three stages of labor.

Video: Premature Births and the Neonatal Intensive Care Unit

Discussion Questions

1. What are some advances in care that technology has provided to the NICU?
2. The speaker discusses several reasons why babies might end up in the NICU. List some of the causes and highlight those that can be controlled by the mother as well as those that cannot be controlled by the mother.
3. What are some short-term and long-term complications that premature babies might encounter?

Video: Habituation

Discussion Questions

1. What evidence suggests that even young infants can grasp fundamental concepts related to numbers? How does this change our thinking about perceptual and cognitive skills?
2. What does “habituation” refer to? How can habituation be used to study an infant’s understanding of configuration, number, or surface area?
3. What practical applications can you think of that would result from studying young infants’ understanding of quantity?

[< Return to Contents](#)

Handout 2-1

Fertility Problems and Solutions

WOMEN

PROBLEM	SOLUTION
Damaged fallopian tubes	Surgery, in vitro fertilization
Abnormal ovulation	Hormone therapy, antibiotics, in vitro fertilization
Pelvic inflammatory disease (PID)	Antibiotics, surgery, change in birth control methods
Endometriosis	Antibiotics, hormone therapy, surgery, artificial insemination
Damaged ovaries	Surgery, antibiotics, hormone therapy
Hostile cervical mucus	Antibiotics, artificial insemination, hormone therapy
Fibroid tumor	Surgery, antibiotics
Stress	Relaxation techniques
Tipped uterus, fibroid tumors	Surgery

MEN

PROBLEM	SOLUTION
Low sperm count	Antibiotics, hormone therapy, artificial insemination, lowered testicular temperature
Dilated veins around testicle	Surgery, lowered testicular temperature, antibiotics
Damaged sperm ducts	Surgery, antibiotics
Hormone deficiency	Hormone therapy
Sperm antibodies	Antibiotics, in vitro fertilization
Chronic illness, alcoholism, drug abuse, long-term use of marijuana	Artificial insemination
Pollutants	Artificial insemination
Stress	Relaxation techniques

Adapted from Jewelewicz, R. (1989). Sexual and reproductive health. In Tapley, D. F., Morris, T. Q., Rowland, L. P., Weiss, R. J., Subak-Sharpe, G. J., & Goetz, D. M (Eds.). *The Columbia University College of Physicians and Surgeons Complete Home Medical Guide* (rev. ed.). New York: Crow.

Handout 2-2

Facts About Conception and Pregnancy

Review your knowledge of conception and pregnancy by answering the questions below.

Conception

1. Trace the journey of the egg in a woman's body:

ovary → _____ → _____

_____ fertilized
_____ unfertilized

2. Trace the journey of sperm cells from ejaculation to conception:

penis → _____ → _____ → _____ → _____

3. List three possible reasons for infertility in women.

- a. _____
- b. _____
- c. _____

4. List two possible reasons for infertility in men.

- a. _____
- b. _____

5. List and define three treatments for infertility.

- a. _____
- b. _____
- c. _____

Pregnancy

1. List three early signs and symptoms of pregnancy.

- a. _____
- b. _____
- c. _____

Handout 2-2, continued

2. Name the three stages of prenatal development. How long does each stage last? What systems have developed? What is the developing child called?

Stage 1: _____	Stage 2: _____	Stage 3: _____
_____	_____	_____
_____	_____	_____
_____	_____	_____

3. List six important components of good prenatal care.

- a. _____
- b. _____
- c. _____
- d. _____
- e. _____
- f. _____

4. Name and describe three prenatal tests.

- a. _____
- b. _____
- c. _____

5. Name six teratogens.

- | | |
|----------|----------|
| a. _____ | b. _____ |
| c. _____ | d. _____ |
| e. _____ | f. _____ |

Handout 2-3

Dominant and Recessive Characteristics

Characteristics in the left-hand column dominate over characteristics listed in the right-hand column.

	DOMINANT TRAITS	RECESSIVE TRAITS
eye coloring	brown eyes	grey, green, hazel, blue eyes
vision	farsightedness normal vision normal vision normal vision	normal vision nearsightedness night blindness color blindness*
hair	dark hair nonred hair curly hair full head of hair widow's peak	blonde, light, red hair red hair straight hair baldness* normal hairline
facial features	dimples unattached earlobes freckles broad lips	no dimples attached earlobes no freckles thin lips
appendages	normal number normal digits normal digits normal joints normal proportion normal thumb normal joints	extra digits fused digits short digits fingers lack 1 joint limb dwarfing clubbed thumb double-jointedness
other	immunity to poison ivy normal pigmented skin normal blood clotting normal hearing normal hearing and speaking normal—no PKU	susceptibility to poison ivy albinism hemophilia* congenital deafness deaf mutism phenylketonuria (PKU)

*sex-linked characteristic

Handout 2-4

Possible Teratogens

This list of suspected teratogens contains many common items. Most babies are born without defects, so the placenta may be an effective barrier. Additionally, the timing of the exposure to a teratogen is critical to its impact on prenatal development. Overall, more damage is likely early in the pregnancy when organ systems are developing.

DISEASES

Chlamydia	Pneumonia	Gonorrhea
Rubella (German Measles)	Herpes	Scarlet Fever
HIV	Syphilis	Mumps
Toxoplasmosis	Tuberculosis	Influenza

DRUGS

Accutane	Hexachlorophene	Alcohol
Iodides	Amphetamines	Lithium
Antibiotics	LSD	Anti-cancer drugs
Opiates	Anticoagulant drugs	Quinine
Aspirin	Sedatives	Barbiturates
Smallpox vaccination	Caffeine	Thalidomide
Nicotine	Tranquilizers	Cocaine
Vitamins in excess	Diethylstilbestrol (DES)	Marijuana

ENVIRONMENTAL FACTORS

Cadmium	Mercury	Cat feces
Nickel	Fumes from paints, solvents, glues, dry-cleaning fluids	Pesticides
Insecticides		Herbicides
Manganese	Radiation (X-rays, video display terminals)	
Hair dyes	Polychlorinated Biphenyls (PCBs)	Lead

NONINFECTIOUS MATERNAL CONDITIONS

Alcoholism	Chemical dependency	Phenylketonuria
Rh + factor	Anemia	Stress
Diabetes mellitus	Young/older mother	

Handout 2-5

Infant Reflexes

Survival Reflexes	
<i>Breathing</i>	Infants reflexively inhale to obtain oxygen and expel carbon dioxide.
<i>Rooting</i>	If you touch an infant's cheek, the infant will turn its head toward the stimulus and open its mouth as if expecting a nipple.
<i>Sucking</i>	If you touch or otherwise stimulate an infant's mouth, the infant will respond by sucking and making rhythmic movements with the mouth and tongue.
<i>Pupillary</i>	The pupils of an infant's eyes narrow when in bright light and when going to sleep, and widen when in dim light and when waking up.
<i>Eye-blink</i>	Infants blink in response to an object's moving quickly toward their eyes or to a puff of air.
Primitive Reflexes	
<i>Moro (startle)</i>	When infants are startled by loud sounds or by being suddenly dropped a few inches, they will first spread their arms and stretch out their fingers, then bring their arms back to their body and clench their fingers.
<i>Palmar</i>	When an infant's palm is stimulated, the infant will grasp tightly and increase the strength of the grasp as the object is pulled away.
<i>Plantar</i>	When an object or a finger is placed on the sole of an infant's foot near the toes, the infant responds by trying to flex the foot.
<i>Babinski</i>	If you stroke the sole of an infant's foot from heel to toes, the infant will spread the small toes and raise the large one.
<i>Stepping</i>	When infants are held upright with their feet against a flat surface and are moved forward, they appear to walk in a coordinated way.
<i>Swimming</i>	Infants will <i>attempt</i> to swim in a coordinated way if placed in water in a prone position.
<i>Tonic neck</i>	When infants' heads are turned to one side, they will extend the arm and leg on that side and flex the arm and leg on the opposite side, as if in a fencing position.

Handout 2-6

Journal Exercise 2.1

If possible, interview your parents or guardians (if this is not possible, try an aunt, or uncle, or grandparent) about your own prenatal development. Use the following questions to get started.

1. Was this a planned pregnancy?
2. Was this your first baby?
3. How did you find out you were pregnant?
4. How did you feel?
5. Were you working?
6. When did you see a doctor?
7. Did you take vitamins?
8. When did you start feeling the baby?
9. When did you begin wearing maternity clothes?
10. What changes did your body go through?
11. What are some of the strongest memories you have of this pregnancy?
12. Did you have any prenatal tests?
13. How did your lifestyle change?
14. Did you smoke? Drink alcohol? Drink coffee or tea? Take any drugs?
15. Did you know the sex of the baby before the birth? Did you have a preference for a boy or a girl?
How did you feel when you found out the sex of your baby?
16. When did you decide on a name for the baby?
17. Did you attend any special classes or workshops about childbirth, nursing, etc.?
18. Did you know of any preexisting conditions?
19. Where were you living?
20. Were there any features or characteristics you were hoping the baby would have? Were there any you were hoping the baby would NOT have?
21. How much of your partner's medical history did you know? In retrospect, how important would that have been?
22. What roles or expectations did you have for this child?
23. What influenced your decision to have a child at this time?
24. Did you have any trouble conceiving? Did you expect to have any trouble becoming pregnant?

Reflect on what you learned. How do you think your own pregnancy (or your partner's) will be (or was) the same or different than your mother's?

Handout 2-7

Reflective Journal Exercise 2.2

You may (a) consult with your parents about your own birth, (b) interview a new parent about her birth experience, or (c) consider the birth of your own child(ren). Please discuss the following in your journal:

1. Describe the events leading up to the delivery. Where did the delivery take place? Who was present? Was any medication used? Was the birth experience as you expected it to be?
2. What was your initial reaction to the newborn? How soon were you able to hold the baby? When did you name the child? If you stayed in a hospital, describe your experience after the birth.
3. What were the first weeks at home like? What problems did you experience? How was having a baby different than you expected? Describe a typical day at home during the first weeks after the baby was born.
